

Quilling

This process is the preparation of the weft threads, and is completed in the form of pirns/quills (cylindrical or slightly tapered support on which yarn is wound)

The pirn or quill is then placed in the shuttle. The latter being the boat-shaped device that carries the weft yarns through the warp yarn in a back-and-forth motion.

The diameter of the threads can vary depending on the products that are to be woven.

There are different machines to do this operation.
